Foreword

SMPTE (the Society of Motion Picture and Television Engineers) is an internationally-recognized standards developing organization. Headquartered and incorporated in the United States of America, SMPTE has members in over 80 countries on six continents. SMPTE's Engineering Documents, including Standards, Recommended Practices, and Engineering Guidelines, are prepared by SMPTE's Technology Committees. Participation in these Committees is open to all with a bona fide interest in their work. SMPTE cooperates closely with other standards-developing organizations, including ISO, IEC and ITU.

SMPTE Engineering Documents are drafted in accordance with the rules given in its Standards Operations Manual. This SMPTE Engineering Document was prepared by Technology Committee 31FS File Formats and Systems.

Normative text is text that describes elements of the design that are indispensable or contains the conformance language keywords: "shall", "should", or "may". Informative text is text that is potentially helpful to the user, but not indispensable, and can be removed, changed, or added editorially without affecting interoperability. Informative text does not contain any conformance keywords.

All text in this document is, by default, normative, except: the Introduction, any clause or subclause explicitly labeled as "Informative" or individual paragraphs that start with "Note:"

The keywords "shall" and "shall not" indicate requirements strictly to be followed in order to conform to the document and from which no deviation is permitted.

The keywords "should" and "should not" indicate that, among several possibilities, one is recommended as particularly suitable, without mentioning or excluding others; or that a certain course of action is preferred but not necessarily required; or that (in the negative form) a certain possibility or course of action is deprecated but not prohibited.

The keywords "may" and "need not" indicate courses of action permissible within the limits of the document.

The keyword "reserved" indicates a provision that is not defined at this time, shall not be used, and may be defined in the future. The keyword "forbidden" indicates "reserved" and in addition indicates that the provision will never be defined in the future.

A conformant implementation according to this document is one that includes all mandatory provisions ("shall") and, if implemented, all recommended provisions ("should") as described. A conformant implementation need not implement optional provisions ("may") and need not implement them as described.

Unless otherwise specified, the order of precedence of the types of normative information in this document shall be as follows: Normative prose shall be the authoritative definition; tables shall be next; then formal languages; then figures; and then any other language forms.

The following changes were made during the revision process:

- The definitions and usages of string types were clarified.
- The lensFirmwareVersion attribute was added.
- The usage of the aperture attribute was clarified.
- The definition of the timecodeRate attribute was clarified.
- The recommended supported size of data window to readers was increased.

Introduction

This clause is entirely informative and does not form an integral part of this Engineering Document.

The ACES image container is a digital data file format that is designed for storing the individual frames of a motion picture during production and for archival use. During production, it is important to maintain the highest possible image quality, and to minimize generational loss as images are repeatedly extracted from files, processed, and stored in new files. Fast random access to individual frames is highly desirable. Storage space and data transmission bandwidth limitations tend to be of secondary concern.

The ACES image container is not meant for distribution of motion pictures to theaters and home viewers, where representation of an entire movie as a single file, compact storage and data security take precedence.

Each ACES image container file contains a single monoscopic or stereoscopic image. Moving images are represented as sequences of image container files, with a separate image container file for each frame. This allows each frame to be read or written individually, without accessing other frames or any kind of enclosing image sequence container.

The ACES image container file format is derived from the popular OpenEXR file format and is readable by many OpenEXR readers.

At the time of publication, no notice had been received by SMPTE claiming patent rights essential to the implementation of this Engineering Document. However, attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. SMPTE shall not be held responsible for identifying any or all such patent rights.

1 Scope

This standard specifies the ACES image container file format, which is used for the exchange of digital images encoded according to SMPTE ST 2065-1, Academy Color Encoding Specification (ACES).

2 Normative references

The following standards contain provisions that, through reference in this text, constitute provisions of this standard. Dated references require that the specific edition cited shall be used as the reference. Undated citations refer to the edition of the referenced document (including any amendments) current at the date of publication of this document. All standards are subject to revision, and users of this engineering document are encouraged to investigate the possibility of applying the most recent edition of any undated reference.

3 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

3.1

altitude

height where the chosen reference surface is mean sea level

[SOURCE: ISO 6709:2008]

3.2

byte order

ordering of bytes for multi-byte data primitives within a file, such as 4-byte integers, or 8-byte floats

3.3

channel

collection of all values of the same name in an image or in a part of an image

3.4

character

member of a set of elements used for the organization, control, or representation of textual data

Note 1 to entry: A character can be represented by a sequence of one or several coded characters.

[SOURCE: ISO/IEC 10646, modified — Note 1 to entry has been added.]

3.5

compositing

combining two images into a single image

[SOURCE: ISO/IEC 15444-2:2004]

3.6

editor

device that is both a compliant reader and a compliant writer and that updates files, or reads files and writes new files with derived contents

3.7

exposure time

time from the start of light exposure integration at a point on the sensor to the end of light exposure integration at that same point on the sensor

3.8

geodetic latitude

angle from the equatorial plane to the perpendicular to the ellipsoid through a given point, northwards treated as positive

[SOURCE: ISO 19111:2019]

3.9

geodetic longitude

angle from the prime meridian plane to the meridian plane of a given point, eastward treated as positive

[SOURCE: ISO 19111:2019]

3.10

length-counted string

int followed by a sequence of bytes, where the int contains the number of bytes in the sequence

Note 1 to entry: Length-counted strings are used in the stringVector attribute type.

3.11

little-endian byte order

byte order having increasing numerical significance with increasing byte address (from the least significant byte to the most significant byte)

3.12

monoscopic image

image containing a single view of the depicted scene, intended to be presented to the viewer on a 2D display device

3.13

null-terminated string

sequence of non-zero bytes followed by a byte with value zero

Note 1 to entry: Null-terminated strings are used in the attribute name, the attribute type name, and the

chlist attribute.

3.14

"over" compositing operation

compositing, where a foreground RGB color F with an associated alpha value A over a background RGB color B, will produce a combined color C, where C = F + (1 - A) *B

[SOURCE: Porter-Duff, 1984]

3.15

pixel aspect ratio

pixel width divided by pixel height when the image is displayed with the intended aspect ratio, where the pixel width is the distance between the centers of two horizontally adjacent pixels on the display, and the pixel height is the distance between the centers of two vertically adjacent pixels on the display

3.16

pixel space

two-dimensional Cartesian coordinate system having signed integer coordinates with x coordinates increasing from left to right and y coordinates increasing from top to bottom

3.17

reader

device consuming files compliant with this standard

3.18

recorder

device that stores image data and image metadata received from a digital capture system

3.19

RGB

color model with red, green, blue components

3.20

scan line

row of pixels, with all pixels having the same y coordinate

3.21

stereoscopic image

image containing two separate views of the depicted scene, intended to be presented to the viewer on a 3D display device such that the left-eye view and right-eye view are visible only to the viewer's left and right eye respectively

3.22

window

axis-parallel rectangular region in pixel space, specified by the coordinates of two opposing corners, (x_{min}, y_{min}) and (x_{max}, y_{max}) , where $x_{min} < x_{max}$ and $y_{min} < y_{max}$, and including all pixels with coordinates (x, y) where $x_{min} \le x \le x_{max}$, and $y_{min} \le y \le y_{max}$

3.23

writer

device producing files compliant with this standard

4 General

4.1 Image

This standard defines the ACES image container file format.

An ACES image container file (referred to as "file" throughout this document) shall contain exactly one image.

The image shall be an RGB image, monoscopic or stereoscopic, with or without Alpha channels. Subclause 4.2 specifies, for each type of image, the channels that are present in the file.

The red, green, and blue components of pixels shall be as defined in SMPTE ST 2065-1 (Academy Color Encoding Specification).

The alpha value of a pixel shall be as defined in 4.3.

The image shall contain one value for each channel of each pixel in the data window.

The red, green, blue, and alpha values are of type half (16-bit floating-point).

Subclause 6.7 describes how pixel data and channels are organized into scan lines.

Annex A lists the attribute values of a sample file along with a hex dump of the beginning of the sample file.

Annex B lists the Media Type registration of the ACES image container file format with IANA.

4.2 Image channels

The type of image determines the channels present in the file:

- A monoscopic image without alpha shall contain channels "B", "G", and "R".
- A monoscopic image with alpha shall contain channels "A", "B", "G", and "R".
- A stereoscopic image without alpha shall contain channels "B", "G", "R", "left.B", "left.G", and "left.R".
- A stereoscopic image with alpha shall contain channels "A", "B", "G", "R", "left.A", "left.B", "left.G" and "left.R".

NOTE

OpenEXR allows an arbitrary number of image channels. The ACES image container restricts the set of image channels that can appear in a file to the four possibilities listed in the above bullet points in this subclause.

Channels "B", "G", and "R" shall represent the blue, green, and red components of the pixel of the monoscopic image or in the right-eye view.

EXAMPLE

The collection of all R values of all pixels in a scan line is the "R channel" of that scan line.

Channels "left.B", "left.G" and "left.R" shall represent the blue, green, and red components of the pixel in the left-eye view.

Channel "A" shall represent alpha of the pixel of the monoscopic image or in the right-eye view.

Channel "left.A" shall represent alpha of the pixel in the left-eye view.

The channel order in scan lines and in the channels attribute shall be "A", "B", "G", "R", "left.A", "left.B", "left.G", "left.R".

4.3 Alpha channel

When an Alpha channel is not present, all pixels are fully opaque.

When an Alpha channel is present, it contains the Alpha value of the pixel.

The alpha values shall be in the range [0.0, 1.0]. A value of 0.0 shall indicate that the pixel is fully transparent, and 1.0 shall indicate that the pixel is fully opaque.

The pixel's RGB values shall specify the amount of color that the pixel shall contribute if used in an "over" compositing operation. This is illustrated in Formula (1).

$$Composite = Foreground + (1 - \alpha) \times Background \tag{1}$$

where

Composite is the resulting set of RGB values, combining an ACES image pixel with a

background

Foreground is the set of RGB values of the ACES image pixel

 α is the Alpha value of the ACES image pixel

Background is another set of RGB values with which the ACES image pixel is composited

- NOTE 1 For compatibility with OpenEXR, and contrary to a typical definition of "premultiplied alpha," the definition specified in this subclause allows for Foreground RGB values > 0 for alpha = 0. Other documents can contain workflow-specific requirements on preparing RGB values prior to storing them in the file. Further, the definition specified in this subclause is not related to "straight alpha" or "unassociated alpha".
- NOTE 2 For operations that work on "straight alpha" instead of "premultiplied alpha", any RGB values premultiplied by a non-zero alpha value can be restored by dividing the RGB values by that alpha value.
- NOTE 3 A foreground image can contain zero and non-zero RGB pixel values and zero and non-zero alpha values, and no masking is needed. Foreground RGB values > 0 for alpha = 0 are useful for semi-transparent sources of light, such as fire with semi-transparent smoke, head-up displays, glow, lens flare, or window reflections.

4.4 Display window, data window

Two windows specify the boundaries of the image:

- The display window shall define the window that is to be displayed.
- The data window shall define the window for which pixel data are available in the file.

No specific spatial relationship between the data window and the display window is required. The two windows may be coincident, they may overlap, or they may be completely disjointed.

EXAMPLE 1

Assume that a motion picture is produced with a resolution of 2048 by 1080 pixels. The upper left and lower right corners of the display window for all frames of the movie are at (0, 0) and (2047, 1079). For most images, in particular finished frames that will be part of the final product, the data window is the same as the display window, but for some images that are used in producing the finished frames, the data window differs from the display window.

EXAMPLE 2

For a background plate that will be heavily post-processed, extra pixels beyond the edge of the display window are recorded. The upper left and lower right corners of the data window are at (-100, -100) and (2147, 1179). The extra pixels are not normally displayed. Their existence allows operations such as large-kernel blurs or simulated camera shake to avoid edge artifacts.

EXAMPLE 3

Alternatively, while working on a computer-generated element, an artist can repeatedly render the same frame. To save time, the artist can render only a small region of interest, and the resulting image files contain no pixel data outside this region of interest. When the image is displayed, the area that is inside the display window but outside of the data window can be filled with an arbitrary color.

4.5 Scan lines

The pixels in the data window shall be stored as scan lines. A data window with opposing corners (x_{min} , y_{min}) and (x_{max} , y_{max}) shall contain

$$y_{max} - y_{min} + 1$$

scan lines. Each scan line shall contain

$$x_{max} - x_{min} + 1$$

pixels.

4.6 Screen window

The screen window is the boundary (left-right and top-bottom) of the camera's view of the scene, and it establishes a relationship between the camera's view of the scene and the file's display window. The screen window is a rectangle in a screen window coordinate system.

The screen window coordinate system shall be a left-handed, Cartesian coordinate system.

Its x-axis shall point in the same direction (to the right) as the x-axis in the display window (which is in pixel space).

Its y-axis shall point in the opposite direction (up) of the y-axis in the display window.

SMPTE ST 2065-4:2023

Its z-axis shall point in the viewing direction, into the scene.

The camera shall be at location {0, 0, 0} and shall look along the positive z-axis.

The screen window shall be an axis-aligned rectangle on the z = +1 plane.

The screen window's rectangle shall map to the display window's rectangle (the latter in pixel space).

The camera's view of the scene as shown in the display window is then the scene cropped by the screen window boundary at the z = +1 plane.

The screen window's rectangle is specified by its width and center position.

The screen window's width W shall be the width of the rectangle in the screen window coordinate system.

The screen window's center C shall be the x and y coordinates of the rectangle's center in the screen window coordinate system.

NOTE 1 The screen window height can be derived according to Formula (21).

$$H = \frac{W \cdot dH}{dW \cdot pR} \tag{2}$$

where

H is the screen window height being calculated

W is the screen window width

dH is the display window height

dW Is the display window width

pR is the pixel aspect ratio

The coordinates of the corners of both the screen window and the display window can be computed according to Formula (3):

$$\{x, y\} = \left\{\frac{C.x \pm W}{2}, \frac{C.y \pm H}{2}\right\}$$
 (3)

where

x, y are the coordinates of the corners being calculated

C.x is the x coordinate of the screen window center

C.y is the y coordinate of the screen window center

W is the screen window width

H is the screen window height

NOTE 2 The screen window coordinate system is different from the coordinate systems used in 8.13 (cameraViewingDirection) and 8.10 (cameraPosition). The screen window coordinate system is locked with the pixel space and is dimensionless, so the z = +1 plane can be thought of as being placed at any distance from the camera including behind the scene.

EXAMPLE

If $C = \{0, 0\}$ and W = 1, then the horizontal viewing angle is 53 degrees, and the camera is aligned with the center of the image.

Figure 1 shows the window coordinate systems, with screen window at z = +1.

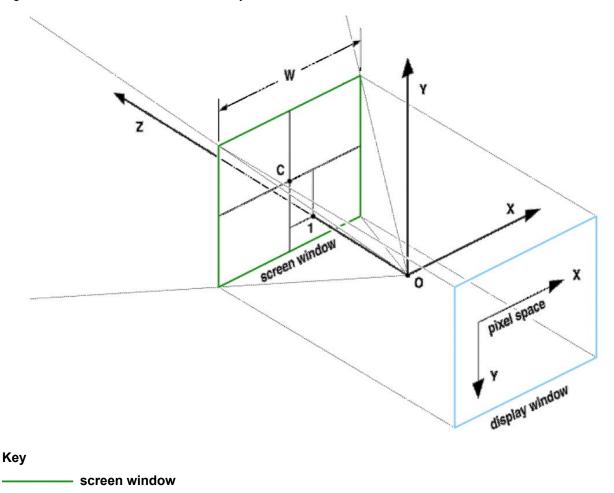

Figure 1 — Window coordinate systems (showing the screen window at z = +1).

display window

5 Basic data types

5.1 Grouping

An ACES image container file shall be a sequence of 8-bit bytes.

Groups of bytes represent basic objects such as integral numbers, floating-point numbers, and strings. Those objects are grouped together to form compound objects such as attributes, or scan lines.

5.2 Packing

All multi-byte basic data types shall be stored in little-endian byte order.

Data in the file shall be densely packed. The file shall contain no "padding" bytes whose only purpose is to ensure alignment of other objects at file locations divisible by some power of two.

NOTE Consider the following C struct:

```
struct SI
{
    short s;
    int i;
};
```

On most computers, the in-memory representation of the SI object occupies eight bytes: 2 bytes for s, 2 padding bytes to ensure four-byte alignment of i, and 4 bytes for i. In an ACES image container file an equivalent object consumes only six bytes: 2 bytes for s and 4 bytes for i. The two padding bytes are not included in the file.

5.3 Integer numbers

Integer numbers can be signed or unsigned. Signed numbers shall be represented using two's complement.

Integer numbers shall be as defined in Table 1.

Table 1 — Integer data types.

Name	Signed	Size in bytes
unsigned char	no	1
Short	yes	2
unsigned short	no	2
Int	yes	4
unsigned int	no	4
unsigned long	no	8

5.4 Floating-point numbers

The representation of floating-point numbers shall conform to the IEEE 754 standard. Floating-point numbers shall be as defined in Table 2.

Table 2 — Floating point data types.

Name	Size in bytes	IEEE 754-2008 format
Half	2	binary16
float	4	binary32
double	8	binary64

5.5 Character encoding

Characters shall be encoded using Unicode UTF-8 encoding in NFC normal form, as defined in the Unicode standard.

NOTE Unicode extends the ASCII character set, and a UTF-8 encoded character can use several bytes, thus the number of characters in a string can be lower than the number of bytes in the same string.

6 File Layout

6.1 File extension

The file name's extension shall be "exr".

NOTE This enables legacy OpenEXR readers to read the file.

6.2 High-level file layout

The file shall contain the components listed in Table 3, concatenated in the order shown in the table.

Table 3 — File structure.

magic number	
version field	
header	
line offset table	
scan line storage	
end-of-file filler	

6.3 Magic number

The magic number shall be first in the file and shall be an int with the value 20 000 630 (decimal).

- NOTE 1 The magic number allows file readers to distinguish ACES and OpenEXR image container files from other files, since the first four bytes of an ACES or OpenEXR image container file are always 0x76, 0x2f, 0x31, and 0x01.
- NOTE 2 In order to maintain compatibility, ACES image container files use the same magic number as OpenEXR files.

6.4 Version field

The version field shall be an int with the value 1026 (decimal) or the value 2 (decimal).

A value of 1026 shall indicate that the file can contain attribute names or attribute type names with a length exceeding 31 bytes.

A value of 2 shall indicate that all attribute names and attribute type names have lengths shorter than 32 bytes.

NOTE

The values specified in this subclause were chosen for compatibility with OpenEXR, where the version field is treated as two separate bit fields. The 8 least significant bits (bits 0 through 7) contain a file format version number. The 24 most significant bits (8 through 31) are treated as a set of Boolean flags.

The current OpenEXR version number is 3, where "current" refers to the version that is compatible with the ACES image container file format.

In OpenEXR bit number 9 of the version field (bit mask 0x200) indicates if the file contains scan lines or tiles. Since the ACES image container format does not support tiles, bit number 9 is always zero.

In OpenEXR, when bit number 10 of the version field (bit mask 0x400) is zero, the length of attribute names, attribute type names, and channel names are limited to 31 bytes. Attribute names and attribute type names in the ACES image container can be longer than 31 bytes, in which case bit 10 is 1. Some older OpenEXR (v1.6) readers do not support value 1.

The remaining 22 flags in the version field are reserved and are zero.

6.5 Header

6.5.1 Header attributes

The header shall be a sequence of attributes, followed by a null byte (0x00).

The size of the header shall not exceed 1 048 576 bytes.

The attributes may occur in any order. No sorting by name or type is required.

6.5.2 Attribute structure

Each attribute shall contain the fields listed in Table 4.

Table 4 — Attribute structure.

attribute name
attribute type name
attribute size
attribute value

The attribute name and the attribute type name shall be null-terminated strings having at least 1 byte and at most 255 bytes not counting the terminating null byte.

The attribute name and the attribute type name shall contain only characters encoded as specified in 5.5 (Character Eencoding).

The attribute name is unique within the file. The file shall not include two or more attributes with equal attribute name strings. Several attributes and their names are defined in Clause 8 (Predefined Aattributes) of this document.

The attribute type name shall specify the type of data stored in the attribute value. Several attribute types and their type names are defined in Clause 7 (Predefined Aattribute Ttypes) of this document.

The attribute size shall be an int specifying the size, in bytes, of the attribute value. The size shall be non-negative.

6.5.3 Required attributes

The header shall contain the attributes listed in Table 5.

The multiView attribute shall be present, when, and only when, the file contains a stereoscopic image. The header may contain other attributes.

Table 5 — Required attributes.

acesImageContainerFlag
channels
chromaticities
compression
dataWindow
displayWindow
lineOrder
pixelAspectRatio
screenWindowCenter
screenWindowWidth

6.5.4 Attribute requirements

Other standards documents can specify additional ACES container attributes and types or impose additional constraints on attributes specified herein.

EXAMPLE 1

A playback specification can mandate that all images in an image sequence have the same values for dataWindow, pixelAspectRatio, and framesPerSecond. An archiving specification can mandate that the uuid attribute be present in every file.

A reader shall be capable of reading a file with an arbitrary set of attributes, including attribute names and types not specified in this standard.

A writer should use the attributes defined in Clause 8, the attribute types defined in Clause 7, or ACES container attributes or types specified in other standards documents, for metadata. When these specifications define no appropriate attribute name or type, a writer may define its own attribute names or types. The names of vendor-specific attributes and types shall comprise a vendor identifier, a period, and a descriptive name.

EXAMPLE 2

"yourCompanyName.yourAttribute"

An editor shall preserve existing attributes and attribute values, except those attributes and attribute values that are obsolete or invalid after the editing operation. The editor shall ensure that all attribute values remain valid and shall remove or recalculate attributes as needed.

NOTE 1 Attributes whose values can get invalidated indirectly by an editing operation include, but are not limited to, headerDigestMD5, imageDigestMD5, originalImageFlag, and uuid.

EXAMPLE 3

To store the exposure time for an image, the predefined expTime attribute is used, but storing an unusual item for which no predefined attribute exists, such as a company-specific billing number, is only possible by defining a new, application-specific attribute.

NOTE 2 The layout of an attribute allows file readers to either skip unknown attributes or to preserve unknown attributes as opaque byte strings.

6.6 Line offset table

The line offset table shall be a sequence of line offsets with one line offset for each scan line of the data window.

Each line offset shall be an unsigned long containing the offset, in bytes, from the start of the file to the start of the corresponding scan line storage. The table entries shall be in ascending order of the scan lines' y coordinate.

- NOTE 1 If the opposing corners of the data window are at (x_{min}, y_{min}) and (x_{max}, y_{max}) , then the line offset table contains $y_{max} y_{min} + 1$ line offsets; the first line offset corresponds to the scan line with y coordinate y_{min} and the last line offset corresponds to scan line with y coordinate y_{max} .
- NOTE 2 The line offset table in the file is redundant; the position of the scan lines in the file can be computed from the data window and the line order attribute. The scan line table is included for compatibility with OpenEXR, where the table is necessary to support random access to scan lines when data compression is used.

6.7 Scan line storage

6.7.1 Scan line objects

The scan line storage shall be a sequence of scan line objects with one scan line object for each scan line of the data window.

The layout of a scan line object shall be as described in Table 6.

Table 6 — Scan line object.

y coordinate
pixel data size
pixel data for first channel
pixel data for last channel

The y coordinate shall be an int specifying the y coordinate of the scan line in the data window.

The pixel data size shall be an int specifying the number of bytes in the pixel data.

The pixel data shall be a sequence of values of type half (16-bit floating-point).

The sequence of values shall be grouped in channels as specified in 4.2, and in the channel order specified in the channels attribute (8.16).

The values of the first channel shall be stored contiguously in ascending order of the pixels' x coordinate, followed by the values for the next channel in ascending order of the pixels' x coordinate, and so on for all channels.

EXAMPLE

17, 24, B0, B1, B2, B3, G0, G1, G2, G3, R0, R1, R2, R3 represents scan line 17 of a monoscopic RGB image with a data window width of 4.

6.7.2 Scan line order

The scan lines are stored according to their y coordinates. The scan lines shall be stored in one of the following orders:

- in increasing y order where scan lines with lower y coordinates (than other scan lines) are stored closer to the beginning of the file, or
- in decreasing y order where scan lines with higher y coordinates are stored closer to the beginning
 of the file.

The scan lines should be stored in increasing order. The scan line order is specified in the lineOrder attribute.

NOTE Pixel y coordinates always increase from top to bottom, regardless of scan line storage order.

6.8 End-of-file filler

The end-of-file filler shall be 0 to 1 048 576 bytes long. It shall contain no meaningful information. The value should be 0. Its sole purpose is to provide readable bytes beyond the last scan line.

NOTE Reading the file can be faster when the end-of-file filler pads the file to a sector boundary. The length of the filler can be determined from the file size.

7 Predefined attribute types

7.1 General

This subclause specifies the data layout for the attribute values of predefined attribute types. The file may include additional attribute types not defined here.

NOTE

These type specifications define only the syntax, not the semantics, of the attribute values. The range and semantics of an attribute value is specified in the attribute definition. See clause 8 (Predefined Aattributes) for these definitions of predefined attributes.

7.2 box2i

Attribute values of type box2i shall have the layout specified in Table 7.

Table 7 — box2i structure.

Field	Data type
xMin	int
yMin	int
xMax	int
уМах	int

7.3 chlist

Attribute values of type chlist shall contain a sequence of channel objects, followed by a null byte (0x00). The layout of a channel object shall be as specified in Table 8.

Table 8 — chlist structure.

Field	Data type
name	null-terminated string having at least 1 and at most 255 bytes not counting the terminating null byte
pixelType	int
pLinear	unsigned int
xSampling	int
ySampling	int

7.4 chromaticities

Attribute values of type chromaticities shall have the layout specified in Table 9.

Table 9 — chromaticities structure.

Field	Data type
red.x	float
red.y	float
green.x	float
green.y	float
blue.x	float
blue.y	float
white.x	float
white.y	float

7.5 compression

Attribute values of type compression shall contain a single unsigned char.

7.6 double

Attribute values of type double shall contain a single double object.

7.7 float

Attribute values of type float shall contain a single float object.

7.8 half

Attribute values of type half shall contain a single half object.

7.9 int

Attribute values of type int shall contain a single int object.

7.10 lineOrder

Attribute values of type lineOrder shall contain a single unsigned char.

7.11 keycode

Attribute values of type keycode shall have the layout and values specified in Table 10 and shall specify the key code information equivalent to key codes as defined in SMPTE ST 254 and SMPTE ST 268-1.

NOTE SMPTE ST 268-1 specifies key codes as ASCII values, while this attribute in this specification uses binary-encoded values.

Table 10 — keyCode structure and values.

Field	Data type	Interpretation	Value range
filmMfcCode	int	film manufacturer code	0 – 99
filmType	int	film type code	0 – 99
prefix	int	prefix to identify film roll	0 – 999 999
count	int	count, increments once every perfsPerCount perforations	0 – 9 999
perfOffset	int	offset of frame, in perforations, from the zero-frame reference mark	1 – 119
perfsPerFrame	int	number of perforations per frame	1 – 15
			NOTE 1 Typical values include: 1 for 16 mm film, 3, 4 or 8 for 35 mm film, 5, 8 or 15 for 65 mm film.
perfsPerCount	int	number of perforations per count	20 – 120
			NOTE 2 Typical values include: 20 for 16 mm film, 64 for 35 mm film, 80 or 120 for 65 mm film.

7.12 rational

Attribute values of type rational shall have the layout specified in Table 11.

Table 11 — rational structure.

Field	Data type	
n	int	
d	unsigned int	

7.13 short

Attribute values of type short shall contain a single short object.

7.14 string

The attribute value of type string shall contain a sequence of bytes.

Unless prescribed otherwise in a specific attribute or use case, the byte sequence shall contain only characters encoded as specified in 5.5 (Character Eencoding).

NOTE As specified in 6.5.2 (Attribute Sstructure), the length of the string is given in the attribute size.

7.15 stringVector

Attribute values of type stringVector shall contain a sequence of zero or more length-counted strings.

Unless prescribed otherwise in a specific attribute or use case, the length-counted strings shall contain only characters encoded as specified in 5.5 (Character Eencoding).

7.16 timecode

Attribute values of type timecode shall have the layout specified in Table 12. The timeAndFlags and userData fields shall represent time code information as defined in SMPTE ST 12-1 and shall be stored as an 8-byte structure as specified for type value 81h (SMPTE ST 12-1 Time Code Metadata) in SMPTE ST 331.

Table 12 — timecode structure.

Field	Data type
timeAndFlags	unsigned int
userData	unsigned int

Table 13 illustrates how the timeAndFlags field is packed for selected frames-per-second systems.

Table 13 — timeAndFlags structure.

Bits	Contents for 24- frames-per-second systems	Contents for 60-fields- per-second systems	Contents for 50-fields-per- second systems
0 – 3	frame units	frame units	frame units
4 – 5	frame tens	frame tens	frame tens
6	unused, 0	drop frame flag	unused, 0
7	unused, 0	color frame flag	color frame flag
8 – 11	seconds units	seconds units	seconds units
12 – 14	seconds tens	seconds tens	seconds tens
15	phase flag	field/phase flag	bgf0
16 – 19	minutes units	minutes units	minutes units
20 – 22	minutes tens	minutes tens	minutes tens
23	bgf0	bgf0	bgf2
24 – 27	hours units	hours units	hours units
28 – 29	hours tens	hours tens	hours tens
30	bgf1	bgf1	bgf1
31	bgf2	bgf2	field/phase flag

The userData field contains user-defined data and control codes, packed as shown in Table 14.

Table 14 — userData structure.

Bits	Contents	
0 – 3	Binary group 1	
4 – 7	Binary group 2	
8 – 11	Binary group 3	
12 – 15	Binary group 4	
16 – 19	Binary group 5	
20 – 23	Binary group 6	
24 – 27	Binary group 7	
28 – 31	Binary group 8	

In Table 13 and Table 14, the bits are numbered from 0 to 31, with 0 referring to the least significant bit and 31 to the most significant bit.

7.17 unsignedChar

Attribute values of type unsignedChar shall contain a single unsigned char object.

7.18 unsignedInt

Attribute values of type unsignedInt shall contain a single unsigned int object.

7.19 unsignedLong

Attribute values of type unsignedLong shall contain a single unsigned long object.

7.20 unsignedShort

Attribute values of type unsignedShort shall contain a single unsigned short object.

7.21 v2f

Attribute values of type v2f shall have the layout specified in Table 15.

Table 15 — v2f structure.

Field	Data type	
Х	float	
У	float	

7.22 v3f

Attribute values of type v3f shall have the layout specified in Table 16.

Table 16 — v3f structure.

Field	Data type
Х	float
У	float
Z	float

8 Predefined attributes

8.1 General

This subclause specifies predefined attributes and the type and semantics of their attribute values. Files may include additional attributes not defined here.

8.2 aceslmageContainerFlag

The acesImageContainerFlag attribute shall be of type int and shall contain the value 1. Values other than 1 are reserved. This attribute and value shall indicate that the file and all attribute values are compliant with this specification. Subclause 6.5.3 (Required Aattributes) specifies that this attribute is required.

- NOTE 1 A writer cannot indicate compliance by merely setting the flag, without providing compliant attribute values.
- NOTE 2 This flag is absent in OpenEXR files, which by coincidence can have attribute values compliant with the specification.

8.3 altitude

The altitude attribute shall be of type float and shall specify the altitude of the location where the image was created or captured. Altitude shall be specified in meters.

8.4 aperture

The aperture attribute shall be of type float and shall specify the T-stop setting of the lens or the F-number setting of the lens. If both T-stop and F-number are known, the T-stop should be specified.

- NOTE 1 The T-stop is the calibrated F-number corrected by a manufacturer for actual light transmission of all of the lens elements, rather than the nominal aperture opening size.
- NOTE 2 In general, the F-number is the focal length of the lens divided by the diameter of the entrance pupil.

8.5 cameraFirmwareVersion

The cameraFirmwareVersion attribute shall be of type string and shall specify the firmware version of the camera. The string shall contain at least one character.

8.6 cameraldentifier

The cameraIdentifier attribute shall be of type string and shall identify this camera uniquely among all cameras from all vendors. The string shall contain at least one character.

- NOTE 1 This can be the camera's MAC address, or a concatenation of fully defined cameraMake, cameraModel, cameraSerialNumber, etc.
- NOTE 2 Files compliant with SMPTE 2065-4:2013 can have a cameraldentifier with zero-length field which is not compliant with this version of the specification.

8.7 cameraLabel

The cameraLabel attribute shall be of type string and should describe how the camera is used or assigned. The string shall contain at least one character.

EXAMPLE

"Camera 1 Left", "B Camera", or "POV"

8.8 cameraMake

The cameraMake attribute shall be of type string and shall specify the manufacturer or vendor of the camera. The string shall contain at least one character.

8.9 cameraModel

The cameraModel attribute shall be of type string and shall specify the model name or model number of the camera. The string shall contain at least one character.

8.10 cameraPosition

The cameraPosition attribute shall be of type v3f and shall specify the x, y, and z position of the camera, in meters. This attribute can be used to record the position of a stationary camera or to track a moving camera. The attribute shall record either the center of the camera's sensor or the center of the entrance pupil of the lens.

The coordinate system for the camera's position shall be fixed in relation to the set and shall be a right-handed, Cartesian coordinate system with the z-axis pointing upwards, and the y-axis pointing 90 degrees to the left of the x-axis direction.

- NOTE 1 Recording the position of the center of the entrance pupil provides the most usable value for example when panning. However, this position changes with lens and focus. For cases when this precision is not needed, recording the center of the sensor is provided as an alternative.
- NOTE 2 For highest precision, the chosen coordinate system is usually NOT the GPS system, but an on-set coordinate system. Any coordinate system can be chosen for recording the camera's position, as long as its axes are orthogonal, and z points up. The coordinate system can be moving with the set, for example, when on a ship. Its reference point (usually assigned position 0,0,0) can be within or outside the set.

8.11 cameraSerialNumber

The cameraSerialNumber attribute shall be of type string and shall specify the serial number of the camera. The string shall contain at least one character.

8.12 cameraUpDirection

The cameraUpDirection attribute shall be of type v3f and shall specify the up direction of the camera.

When the cameraUpDirection attribute is present, the cameraViewingDirection attribute shall also be present.

The v3f structure shall specify the x, y, z values for the camera's "up" direction. The up direction shall be perpendicular to the direction specified in the cameraViewingDirection attribute. The coordinate system for the camera's up direction shall be the coordinate system defined for the cameraViewingDirection attribute.

8.13 cameraViewingDirection

The cameraViewingDirection attribute shall be of type v3f and shall specify the viewing direction of the camera.

The v3f structure shall specify the x, y, z values for the viewing direction of the camera (the direction of the optical axis of the lens).

The coordinate system for the camera's direction shall be a right-handed, Cartesian coordinate system with the z-axis pointing upwards, and the y-axis pointing 90 degrees to the left of the x-axis direction. No units are specified, nor needed, for this coordinate system.

When the cameraPosition attribute is present, the axes of the cameraViewingDirection coordinate system shall be parallel to, and point in the same direction as, those of the cameraPosition coordinate system.

When the cameraPosition attribute is not present, the directions of the axes in the coordinate system are undefined.

When the cameraViewingDirection attribute is present, the cameraUpDirection attribute shall also be present.

When the cameraViewingDirection attribute is not present, the camera's viewing and up directions are undefined.

NOTE

The methods for converting measured intrinsic rotational angles (heading, elevation, bank; or yaw, pitch, roll; or roll, pitch, yaw) to the cameraViewingDirection are out of scope for this specification as they are specific to the order in which the rotations are applied to the camera mount.

8.14 capDate

The capDate attribute shall be of type string and shall specify the time when the image was created or captured. The time shall be given in local time. The string shall be 19 bytes long and shall be formatted as

YYYY:MM:DD hh:mm:ss

where YYYY is the year (4 digits, e.g., 2011), MM is the month (2 digits, 01, 02, ... 12), DD is the day of the month (2 digits, 01, 02, ... 31), hh is the hour (2 digits, 00, 01, ... 23), mm is the minute, and ss is the second (2 digits each, 00, 01, ... 59). DD and hh shall be separated by one space character.

8.15 captureRate

The captureRate attribute shall be of type rational and shall specify the capture rate of the image sequence to which the image belongs. This can be used for variable frame rates and time-lapse photography, and for any clock rate. The capture rate shall be specified in frames per second. The capture rate shall be specified as a rational number, n/d, where both n and d shall be greater than zero.

The value of the capture rate shall be calculated as in Formula (4).

$$r = \frac{1}{t_n - t_{n-1}} \tag{4}$$

where

r is the capture rate, in frames per second

 t_n is the time of a frame

 t_{n-1} is the time of the previous frame

The time of a frame shall be the time of the center of the frame's exposure interval, in seconds.

If there is no previous frame, the rate may be calculated as if such a frame existed at a desired time.

NOTE captureRate is stored as a rational number in order to allow exact representation of NTSC frame and field rates.

8.16 channels

The channels attribute shall be of type chlist and shall contain three to eight channel objects, depending on the type of image, as defined in 4.1. Subclause 6.5.3 (Required Aattributes) specifies that this attribute is required.

For a monoscopic RGB image without alpha, the name fields in the channel objects shall be "B", "G", and "R", respectively.

For a monoscopic RGB image with alpha, the name fields in the channel objects shall be "A", "B", "G," and "R", respectively.

For a stereoscopic RGB image without alpha, the name fields in the channel objects shall be "B", "G", "R", "left.B", "left.G", and "left.R", respectively.

For a stereoscopic RGB image with alpha, the name fields in the channel objects shall be "A", "B", "G", "R", "left.A", "left.B", "left.G", and "left.R", respectively.

In all chlist objects, the pixelType, xSampling and ySampling values shall be 1, and the pLinear value shall be 0.

NOTE

The fields pixelType, pLinear, xSampling, ySampling have fixed values in ACES-compliant channel objects. The pixelType value 1 indicates that pixel values are stored in half-float format. The xSampling and ySampling values 1 indicate no subsampling. The pLinear value 0 indicates linearly encoded pixel values.

8.17 chromaticities

The chromaticities attribute shall be of type chromaticities and shall contain the chromaticity values of the ACES RGB primaries and the ACES RGB white point as defined in SMPTE ST 2065-1. Subclause 6.5.3 (Required Aattributes) specifies that this attribute is required.

These values are shown in Table 17.

red.x = 0.73470 red.y = 0.26530 green.x = 0.00000 green.y = 1.00000 blue.x = 0.00010 blue.y = -0.07700 white.x = 0.32168 white.y = 0.33767

Table 17 — chromaticities values.

8.18 comments

The comments attribute shall be of type string, and may contain image information in human readable form, for example, a verbal description of the image, or notes related to the production or intended use of the image. The attribute shall not be used in place of any other predefined attribute. The format of the string is undefined. The string shall contain at least one character.

8.19 compression

The compression attribute shall be of type compression and shall contain the value 0, indicating no compression. Subclause 6.5.3 (Required Aattributes) specifies that this attribute is required.

8.20 convergenceDistance

The convergenceDistance attribute shall be of type float and shall specify the distance in meters from the baseline of the two lens entrance pupils to the point where the lens axes would cross each other. A positive value shall indicate a point in front of this baseline. For orthogonal stereo images, this value shall be a positive-infinity floating-point value.

8.21 creator

The creator attribute shall be of type string and shall specify the creator of the image. The string shall contain at least one character.

8.22 dataWindow

The dataWindow attribute shall be of type box2i and shall specify the data window, with xMin and yMin defining the upper left corner and xMax and yMax defining the lower right corner. Subclause 6.5.3 (Required Aattributes) specifies that this attribute is required.

8.23 displayWindow

The displayWindow attribute shall be of type box2i and shall specify the display window, with xMin and yMin defining the upper left corner and xMax and yMax defining the lower right corner. Subclause 6.5.3 (Required Aattributes) specifies that this attribute is required.

8.24 expTime

The expTime attribute shall be of type float and shall specify the exposure time for the image, in seconds.

8.25 focalLength

The focalLength attribute shall be of type float and shall specify the focal length of the lens, in millimeters, when the image was created or captured.

8.26 focus

The focus attribute shall be of type float and shall specify the focus distance, in meters, when the image was captured. Focus distance shall be from the camera's film or sensor plane. If the lens was focused at its hyper-focal setting, the value may be the hyper-focal distance or a positive-infinity floating-point value.

8.27 framesPerSecond

The framesPerSecond attribute shall be of type rational and shall specify the nominal playback rate of the image sequence to which the image belongs. The playback rate shall be specified in frames per second. The playback rate shall be a rational number; n/d. n and d shall both be greater than zero.

NOTE 1 framesPerSecond is stored as rational number in order to allow exact representation of NTSC frame and field rates, as well as "film-like" frame rates that synchronize with NTSC frame rates. Some commonly used frame rates include 24000/1001, 24/1, 25/1, 30000/1001, 30/1, 48000/1001, 48/1, 50/1, 60000/1001 and 60/1.

NOTE 2 The attribute name was chosen for compatibility with OpenEXR.

8.28 free

The free attribute shall be of type string. It can be used for storage alignment or to reserve space for additional attributes. The string shall contain no meaningful information. Each byte in the string should be equal to 0x00.

NOTE Reading the file can be faster when the free attribute is used to align the scan line storage in a set of files to start at the same offset or on a sector boundary.

8.29 imageDigestMD5

The imageDigestMD5 attribute shall be of type string and shall be an MD5 message digest of the scan line storage area, calculated as specified in IETF RFC 1321. The string is 128 bits long.

NOTE An edit of pixel data will result in a different digest value.

8.30 imageCounter

The imageCounter attribute shall be of type int and shall specify an image number. For a sequence of images, the image number shall be increasing when the images are accessed in the intended play order.

NOTE imageCounter can be used to uniquely identify frames of high-speed photography that would have identical time codes.

8.31 imageRotation

The imageRotation attribute shall be of type float and shall specify a rotation of the image in degrees. The value shall be in the range [-45, +45]. The center of rotation shall be the center of the display window. A positive value shall specify a rotation from x-axis towards y-axis.

8.32 interocular Distance

The interocularDistance attribute shall be of type float and shall specify the distance in meters along the baseline between the centers of entrance pupils of the two lenses. A negative value can reflect a reversal of the eye positions of the cameras.

8.33 isoSpeed

The isoSpeed attribute shall be of type float and shall specify the exposure index (EI) rating of the camera when the image was captured.

NOTE The ISO standard ISO 12232:2019 provides techniques for determining the exposure index rating.

8.34 keyCode

The keyCode attribute shall be of type keyCode and shall specify the key code of the image.

8.35 latitude

The latitude attribute shall be of type float and shall specify the geodetic latitude of the location where the image was created or captured. Latitude shall be specified in decimal degrees.

8.36 lensAttributes

The lensAttributes attribute shall be of type string. The string shall contain at least one character. The string may contain lens metadata not specified in other predefined attributes (such as aperture, focus, focalLength, lensMake, lensModel, lensSerialNumber). The attribute shall not be used in place of any other predefined attribute. The format of the string is undefined.

The file may include additional lens attributes. The attribute name shall be a vendor-specific prefix followed by ".lensAttributes". The attribute shall meet the requirements of the lensAttributes attribute.

8.37 lensFirmwareVersion

The lensFirmwareVersion attribute shall be of type string and shall specify the firmware version of the lens. The string shall contain at least one character.

8.38 lensMake

The lensMake attribute shall be of type string and shall specify the manufacturer or vendor of the lens. The string shall contain at least one character.

8.39 lensModel

The lensModel attribute shall be of type string and shall specify the model name or model number of the lens. The string shall contain at least one character.

8.40 lensSerialNumber

The lensSerialNumber attribute shall be of type string and shall specify the serial number of the lens. The string shall contain at least one character.

NOTE The characters in the string can include digits as well as non-digits.

8.41 lineOrder

The lineOrder attribute shall be of type lineOrder and shall specify the order in which the scan lines are located in the file. The attribute value shall be either 0 indicating increasing y line order or 1 indicating decreasing y line order. The value should be 0. Subclause 6.5.3 (Required Aattributes) specifies that this attribute is required.

NOTE

Pixel y coordinates always increase from top to bottom. The direction of the y-axis is not affected by the lineOrder attribute. This attribute indicates only the storage order of rows in the scan line area.

8.42 longitude

The longitude attribute shall be of type float and shall specify the geodetic longitude of the location where the image was created or captured. Longitude shall be specified in decimal degrees.

8.43 metadataDigestMD5

The metadataDigestMD5 attribute shall be of type string and shall be an MD5 message digest, calculated as specified in IETF RFC 1321. The string is 128 bits long. The input to the digest calculation shall be the sequence of bytes starting with the first byte of the file and ending with the last byte in the line offset table. The input to the digest calculation shall have a metadataDigestMD5 attribute value with all bits equal to zero.

NOTE A reorder or edit of the attributes will result in a different digest value.

8.44 multiView

The multiView attribute shall be of type stringVector and shall contain the two strings "right" and "left", in that order. Subclause 6.5.3 (Required Aattributes) specifies that this attribute is required for stereoscopic images.

8.45 originallmageFlag

The originalImageFlag attribute shall be of type int. The attribute value shall be 1 if the pixel data is an unaltered original from a source such as an electronic camera, a film scanner or a computer-graphics rendering engine. The attribute value shall be 0 if the pixel data has been altered in any way.

Attribute values other than 0 or 1 are reserved.

NOTE

"Unaltered original" does not usually mean "raw image sensor data." Some amount of processing will be necessary to convert raw data from the sensor in an electronic camera or a film scanner into an ACES image container file, but this type of processing is not considered altering the image. The resulting file is still an original.

8.46 owner

The owner attribute shall be of type string and shall specify the owner of the image. The string shall contain at least one character.

8.47 pixelAspectRatio

The pixelAspectRatio attribute shall be of type float and shall specify the intended pixel aspect ratio, defined in 3.15, of the displayed image. The value shall be greater than zero. Subclause 6.5.3 (Required Aattributes) specifies that this attribute is required.

8.48 recorderFirmwareVersion

The recorderFirmwareVersion attribute shall be of type string and shall specify the firmware version of the recorder. The string shall contain at least one character.

8.49 recorderMake

The recorderMake attribute shall be of type string and shall specify the manufacturer or vendor of the recorder. The string shall contain at least one character.

8.50 recorderModel

The recorderModel attribute shall be of type string and shall specify the model name or model number of the recorder. The string shall contain at least one character.

8.51 recorderSerialNumber

The recorderSerialNumber attribute shall be of type string and shall specify the serial number of the recorder. The string shall contain at least one character.

8.52 reelName

The reelName attribute shall be of type string and shall specify a name for a sequence of unique images. The string shall contain at least one character.

NOTE

The value is often a reel name, tape name, clip name, or reel number, and can be used as a source identifier in an EDL (Edit Decision List). Some EDL systems require that the value is restricted to 1-8 alphanumeric characters (A..Z, a..z, 0..9), and including or not including underscore (_).

8.53 screenWindowCenter

The screenWindowCenter attribute shall be of type v2f and shall specify the x and y coordinates of the center of the screen window. Subclause 6.5.3 (Required Aattributes) specifies that this attribute is required.

8.54 screenWindowWidth

The screenWindowWidth attribute shall be of type float and shall specify the width of the screen window. The value shall be greater than zero. Subclause 6.5.3 (Required Aattributes) specifies that this attribute is required.

8.55 storageMediaSerialNumber

The storageMediaSerialNumber attribute shall be of type string and shall specify the serial number of the physical medium on which the camera output is stored. The string shall contain at least one character.

8.56 timeCode

The timeCode attribute shall be of type timecode and shall specify the time code for the image.

8.57 timecodeRate

The timecodeRate attribute shall be of type int and shall specify the nominal playback rate in frames per second, rounded to the nearest integer value. When the nominal playback rate corresponds exactly to the midpoint of two integer values, the timecode rate shall be equal to the value of the nominal playback rate rounded to the nearest higher integer.

8.58 utcOffset

The utcOffset attribute shall be of type float and shall specify the offset of the local time from Universal Coordinated Time (UTC) when the image was created or captured. When the attribute is not present, the UTC offset shall be 0. The offset shall be specified in seconds, such that local time = UTC + UTC offset.

8.59 uuid

The uuid attribute shall be of type string and shall contain a universally unique identifier (UUID) formatted as specified in IETF RFC 4122. The string is 128 bits long. The identifier assigned to the image shall be such that with a very high probability no other image will ever be assigned the same identifier.

9 Attributes for stereoscopic images

The attributes listed in Table 18 may have different attribute values for right and left image.

The name for the right image attribute shall be the name listed in the table.

The name for the left image attribute shall be the prefix "left." followed by the name listed in the table. This prefix corresponds to the naming of image channels.

A left image attribute shall be present only if the attribute values for the right and left images are different.

Table 18 — Names of stereoscopic attributes.

Altitude	aperture	cameraFirmwareVersion
cameraIdentifier	cameraLabel	cameraMake
cameraModel	cameraPosition	cameraSerialNumber
cameraUpDirection	cameraViewingDirection	comments
displayWindow	expTime	focalLength
Focus	imageCounter	isoSpeed
keyCode	latitude	lensAttributes
lensMake	lensModel	lensSerialNumber
longitude	originalImageFlag	pixelAspectRatio
recorderFirmwareVersion	recorderMake	recorderModel
recorderSerialNumber	reelName	screenWindowCenter
screenWindowWidth	storageMediaSerialNumber	timeCode
uuid		

10 Reader and writer recommendations

A reader should support files having a data window of up to 8192 x 8192 pixels and having up to 8 channels. The size of such a file is less than 1100 MB.

Annex A Sample file (informative)

Table A.1 specifies a sample file containing 17 attributes—the 10 required, 5 optional, and custom attributes.

Table A.1 — Sample attribute list.

Attribute name	Туре	Size	Contents
acesImageContainerFlag	int	4	1
channels	chlist	55	R 1 0 1 1
			G 1 0 1 1
			B 1 0 1 1
chromaticities	chromaticities	32	0.7347 0.2653
			0.0000 1.0000
			0.0001 -0.0770

Figure A.1 — Sample hex dump.

SMPTE ST 2065-4:2023

Figure A.2 shows a hex dump of the end of scan line 0 and beginning of scan line 1, starting at 0x54CB and highlighted in blue.

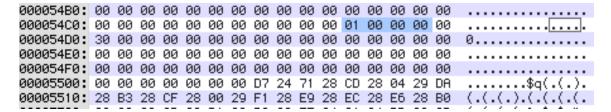

Figure A.2 — Sample hex dump showing end of scan line 0 and beginning of scan line 1.

Annex B Media type registration with IANA (informative)

Table B.1 lists the IANA Media Type registration for reference.

Table B.1 — IANA media type registration.

Media type name:	image
Media subtype name:	aces
Required parameters:	none
Optional parameters:	none
Encoding considerations:	binary
Security considerations:	ACES Image Container files utilize a structure which can store image data and attributes of this image data. The fields defined in the ACES Image Container specification are of a descriptive nature and provide information that is useful to facilitate the viewing and rendering of images by a recipient, along with additional metadata not required for viewing and rendering, but which might be helpful in the use of the image in the context of a larger project, such as the accomplishment of a motion picture or television project. As such, the fields currently defined in the ACES Image Container specification do not in themselves create additional security risks, since the fields are not used to induce any particular behavior by the recipient application. The format does not contain executable code, scripts, or macros. The format contains offset values and count values, which can trigger segmentation faults in applications. The image is not compressed, and the compression attribute is set to No Compression. The format does not include encryption, or other forms of privacy protection. If needed, such would have to be provided externally. The format includes optional MD5 digests for verifying the integrity of metadata and image data.
Interoperability considerations:	ACES Image Container files are scene-referred.
Published specification:	The ACES Image Container is defined by SMPTE ST 2065-4, "ACES Image Container File Layout" published by Society of Motion Picture and Television Engineers (SMPTE)
Application Usage:	Film and Television production and post-production applications, including but not limited to on-set or near-set color correction, editorial, visual effects, and finishing.

SMPTE ST 2065-4:2023

Fragment identifier considerations:	none	
Restrictions on usage:	none	
Provisional registration? (standards tree only):	none	
Additional information:	 Deprecated alias names for this type: N/A Magic number(s): The first 8 bytes (fields magic number and version) are 76 2F 31 01 02 00 00 00 or 76 2F 31 01 02 04 00 00. The attribute acesImageContainerFlag has value 1. File extension(s): exr Macintosh file type code: N/A Object Identifiers: N/A 	
Intended usage:	Common	
Other information & Comments:	ACES images can be stand-alone files or wrapped in container files such as MXF or AXF.
